Security risk assessment report

Part 1: Select up to three hardening tools and methods to implement
1. **Multi-factor authentication (MFA):** Require employees to use a second method of verification when logging in. 2. **Strong passwords:** Require unique passwords and change the database administrator's default password. 3. **Firewall rules:** Configure firewalls to block unwanted traffic and allow only necessary connections.

Part 2: Explain your recommendations
MFA makes it harder for attackers to access accounts, even if they know the password. Strong, unique passwords help prevent unauthorized access to employee accounts and the database. Firewall rules help protect the network by blocking suspicious or unnecessary traffic. MFA should be used every time users authenticate. Passwords should be changed whenever they are weak, exposed, or still set to default values. Firewall rules should be reviewed regularly and updated whenever network needs or security risks change.
